Each process spends the first 20% of execution time doing I/O, the next 70% of time doing computation, and the last 10% of time doing I/O again. Data for Q. 67 & 68 are given below.

Barrier is a synchronization construct where a set of processes synchronizes globally i.e. each process in the set arrives at the barrier and waits for all others to arrive and then all processes leave the barrier. Let the number of processes in the set be three and S be a binary semaphore with the usual P and V functions. Consider the following C implementation of a barrier with line numbers shown on the left.

```
Void barrier(void) {
1   :   P(S)
2   :   Process_arrived++;
3   :   V (S) :
4   :   while (process_arrived' = 3);
5   :   P(S);
6   :   Precess_left++;
7   :   if(process_left == 3)
8   :       process_arrived = 0;
9   :       process_left = 0;
10  :   }
11  :   V(S);
}
```

The variable `process_arrived` and `process_left` are shared among all processes and are initialized to zero. In a concurrent program all the three processes call the barrier function when they need to synchronize globally.

- (D) The barrier implementation is correct if there are only two processes instead of three

Question. 68

Which one of the following rectifies the problem in the implementation?

- (A) lines 6 to 10 are simply replaced by `process_arrived`
- (B) At the beginning of the barrier the first process to enter the barrier waits until `process_arrived` becomes zero before proceeding to execute `P(S)`
- (C) Context switch is disabled at the beginning of the barrier and re-enabled at the end.
- (D) The variable `process_left` is made private instead of shared
